Post-Quantum Lattice-Based Encryption for Secure Communication

---

1. Abstract

Quantum computing introduces significant challenges to traditional cryptographic systems such as RSA and Elliptic Curve Cryptography (ECC), which rely on mathematical problems vulnerable to quantum algorithms like Shor's algorithm. Post-Quantum Cryptography (PQC) aims to design cryptographic schemes that remain secure even against quantum adversaries. Among various PQC approaches, lattice-based cryptography has gained considerable attention due to its strong theoretical security guarantees and practical efficiency.

This project presents the design and implementation of a simplified lattice-based encryption scheme for secure communication. The system demonstrates key generation, encryption, and decryption processes using lattice mathematics. The implementation is developed in Python and shows how lattice-based cryptography can provide quantum-resistant security.

2. Introduction

The increasing development of quantum computing technology threatens classical cryptographic algorithms that rely on number-theoretic assumptions. Algorithms such as RSA and Diffie–Hellman are based on integer factorization and discrete logarithm problems, which can be efficiently solved using quantum computers.

Post-Quantum Cryptography provides solutions that remain secure even in the presence of quantum computing. Lattice-based cryptography is considered one of the most promising candidates because:

- It is resistant to both classical and quantum attacks.
- It offers efficient computation.
- It supports advanced cryptographic primitives.

This project focuses on implementing a simplified lattice-based encryption scheme to demonstrate quantum-secure communication.

3. Objectives

The main objectives of this project are:

1. To understand post-quantum cryptography principles.
2. To design a lattice-based encryption algorithm.
3. To implement key generation, encryption, and decryption.
4. To demonstrate quantum-resistant communication.
5. To analyze security and performance.

4. Background of Lattice Cryptography

A lattice is a mathematical structure consisting of regularly spaced points in multidimensional space.

Mathematically:

$L = \{ a_1b_1 + a_2b_2 + \ldots + a_nb_n \}$

Where:

- $b_1, b_2 \ldots$ are basis vectors
- $a_1, a_2 \ldots$ are integer coefficients

Security of lattice cryptography relies on hard problems such as:

- Shortest Vector Problem (SVP)
- Learning With Errors (LWE)

These problems are believed to be resistant to quantum attacks.

7. Algorithm Design

7.1 Key Generation

1. Generate random matrix A
2. Generate secret vector s
3. Generate error vector e
4. Compute:

$b = A \times s + e$

Public Key = (A, b)
Private Key = s

7.2 Encryption

1. Generate random vector r
2. Generate noise values
3. Compute:

$u = A^T \times r + \text{noise}$
$v = b^T \times r + \text{message}$

Ciphertext = (u, v)

7.3 Decryption

Compute:

$\text{message} = v - s^T \times u$

Recover original message.
